

corner u,v: detector, through a 30 Hz latch, a 1-4 step delay and sticky dropout

visible: -1 sentinel when unseen

roll, pitch: flight controller attitude (nose-down positive on this FC)

gyro: raw counts / 16.384, clipped ± 8 rad/s

velocity: dead-reckoned from issued thrust, attitude and a drag model; never the accelerometer

next gate one-hot: from the gate tracker; nothing on the course publishes it

last actions: the issued command, not the delayed one

51 channels (v1, 1632 inputs) + 4 (v2, 1760). Every value both ends must agree on is hashed: v2 = a20c14d6a335.

A wrong channel order raises nothing; it flies.
